

# Origin determination and traceability: | An overview for gemstones

Presentation by

PD Dr. Michael S. Krzemnicki, Director Swiss Gemmological Institute SSEF

# | TERMS AND THEIR SIGNIFICANCE

The terms Origin and Origin Determination cover many aspects:

- Formation (natural vs synthetic or cultured)
- Geological
- Geographical
- Historical
- Emotional
- Species-related (e.g. CITES)
- Political (boycott) / Sustainability / responsible sourcing

Ruby mining near Bawpadan in Mogok

# | TERMS AND THEIR SIGNIFICANCE

## Traceability:

- Tracing (from market to origin)
- Tracking (from origin to market)

## Challenges, especially for coloured gemstones:

- Mostly informal artisanal mining
- Mostly small short-lived deposits
- Quality main criteria over origin
- Stock management
- Gems are not a commodity (huge amount of historically mined gems)
- Overlapping analytical data for gems from different origins

Tsavorite garnet from Kenya & Tanzania.

# | GEMMOLOGICAL LABORATORY

A gemmological laboratory analyses loose and mounted gems with scientific methods and issues reports giving expert opinions to answer the following questions:

**Identification:** What gemstone ?

**Authenticity:** natural formation or synthetic production ?

**Treatment:** treated or not, what kind of treatment ?

**Origin:** which country/deposit ? (scientifically only possible for certain coloured gemstones)

**Quality:** international standardised grading (commonly only for natural diamonds)

# | ORIGIN DETERMINATION

A multi-step scientific deduction process:

- Inclusion features
- Analysed physical and structural properties
- Trace element composition
- In certain cases radiometric age dating

## First level

Deduction of the geological setting (e.g. marble, amphibolite rock, basaltic rock) in which the gemstone has formed.

## Second level

Based on this, deduction of the best fitting geographic gem producing country/area.

# | ORIGIN DETERMINATION

Finally, a geographic origin determination is always an **expert opinion**, and as such different labs may also come to different results, very similar to fields such as paintings, or antiquities.

But still it is an independent assessment and may be crucial to support or exclude origin claims made in documents or by a client.

# | ORIGIN DETERMINATION

Minerals and Gemstones mostly form in areas where large-scale geological processes shaped the surface of the Earth.

# ORIGIN DETERMINATION

The collision of the Indian plate with the Eurasian continental plate has produced some of the most important sources for coloured gems, such as the sapphires from Kashmir and the sapphires and rubies from Burma, and many more.

# KASHMIR SAPPHIRE

Zanskar © Corto Maltese, Flickr.com

- 1880 sapphire deposit discovered in the Zanskar mountain range in Kashmir (India)
- 1882-1887 main mining activity
- 1888-today only sporadic activity, but no evident production of gem-quality material

# | KASHMIR SAPPHIRE

The Richelieu sapphires,  
sold at Sotheby's Geneva  
for US\$ 8.35 mio.

# | KASHMIR SAPPHIRE

Pargasite (amphibole)  
in sapphire from Kashmir

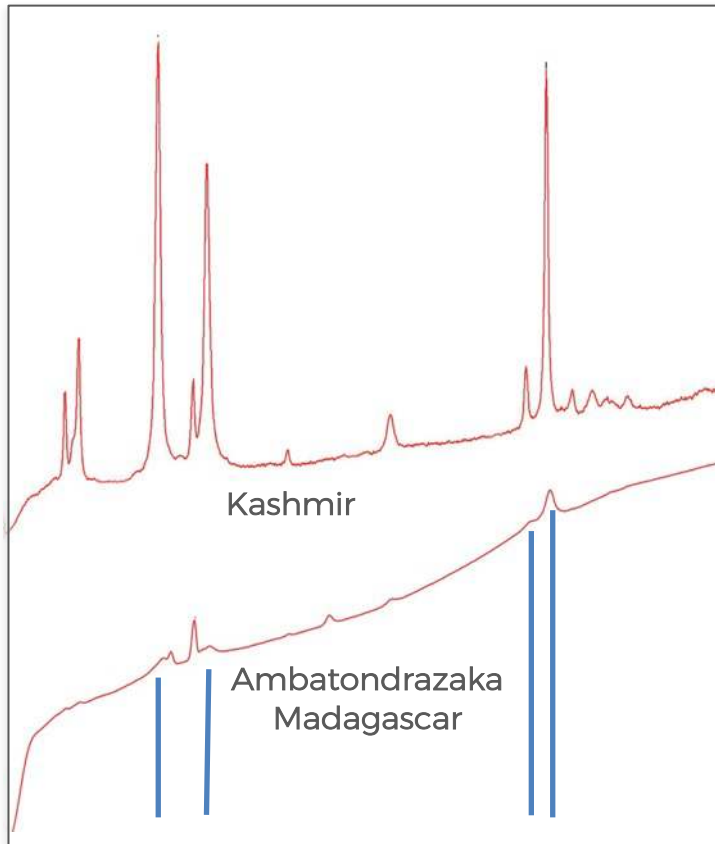

# | KASHMIR SAPPHIRE

‘Kashmir-like’ sapphires of excellent quality from new deposit near Ambatondrazaka, Madagascar.

Raman spectra of zircon inclusions

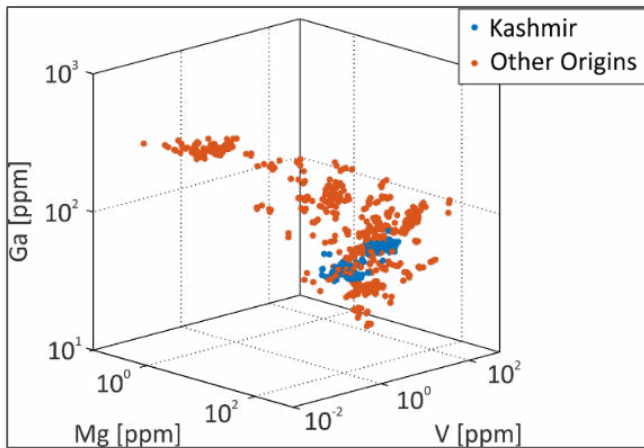

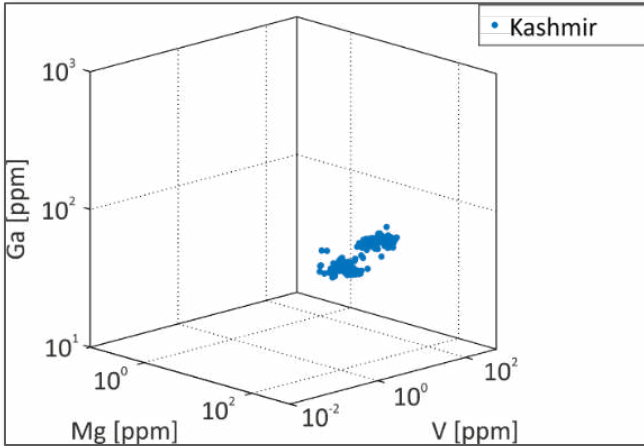

non-metamict zircon inclusions

metamict zircon inclusions

Trace element analyses using laser ablation ICP TOF MS

# | REAL CASE IN THE SSEF LABORATORY

## Natural vs Synthetic Origin

Separation of ruby of natural origin (formation by geological process) from ruby of synthetic origin (produced in a factory, e.g. in Switzerland).

Natural ruby of 22.04 ct from Mozambique  
(named the “Rhino Ruby”)  
ca. 500 million years old

Synthetic ruby of 6.54 ct  
Probably 1-30 years old !

# REAL CASE IN THE SSEF LABORATORY

## Historic Provenance

Documenting scientifically gemstones of historic or iconic significance.

Sapphire of Catherine the Great (331 ct), Empress of the Russian Empire from 1762 to her death in 1796.

Later part of the Harry Winston 'Court of Jewels' collection (see *Harry Winston, the ultimate Jeweler* by Krashes and Winston, 1984, page 27).

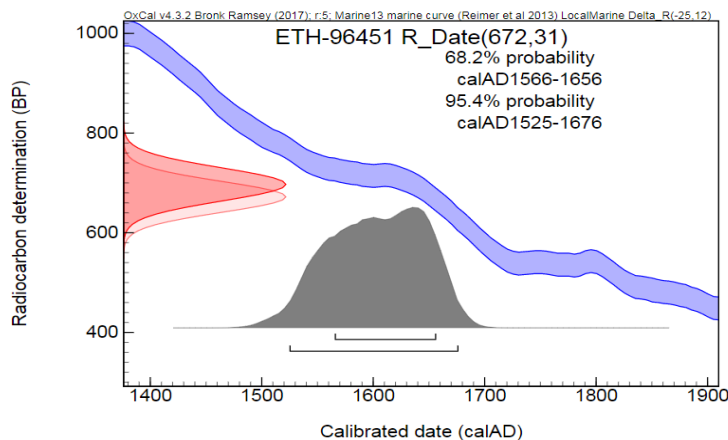

# REAL CASE IN THE SSEF LABORATORY

## Historic Provenance

Supporting evidence by using radiocarbon age dating of a historic pearl.

Documented since mid 19th century, originally belonging to Ana María de Sevilla (1828-1861); probably fished during Hernán Cortéz' conquest of the Aztec empire in the 16<sup>th</sup> century.

Our radiocarbon age dating result (16<sup>th</sup> – 17<sup>th</sup> century) perfectly matches the historic provenance of this pearl.

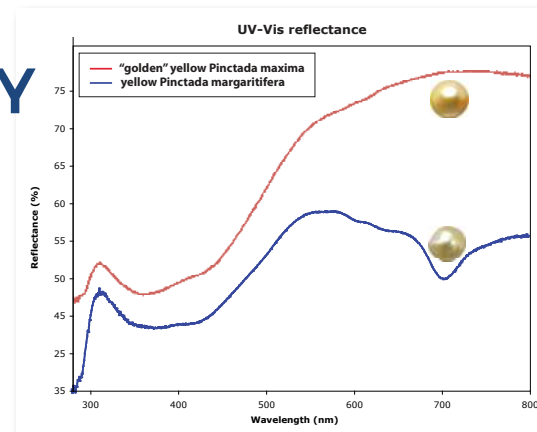

at auction this May in Geneva  
Christie's Magnificent Jewels Lot 264

# REAL CASE IN THE SSEF LABORATORY

Determining biological species by using spectroscopic methods and DNA fingerprinting.

SSEF will soon offer DNA fingerprinting and species identification as a service for pearls, corals, and ivory in collaboration with the IRM University Zurich.

FEATURE ARTICLE

## DNA Fingerprinting of Pearls, Corals and Ivory: A Brief Review of Applications in Gemmology

Laurent E. Cartier, Michael S. Krzemnicki, Bertalan Lendvay and Joana B. Meyer

**ABSTRACT:** This article reviews the extraction of DNA (deoxyribonucleic acid) from biogenic gem materials (pearls, corals and ivory) for determining species identification and geographic/genetic origin. We describe recent developments in the methodology adapted for gem sampling that is minimally destructive, as well as the successful DNA fingerprinting of cultured pearls from various *Pinctada* molluscs to identify their species. The DNA analysis methods presented here can also potentially be used for fingerprinting corals and ivory.

The Journal of Gemmology, 36(2), 2018, pp. 112-140 <http://dx.doi.org/10.1009/jog.2018.36.2.112>  
© 2018 The Gemmological Association of Great Britain

**B**iogenic gems—often called ‘organic gems’ (see Galopin de Carvalho, 2016, for a recent discussion of terminology)—are some of the oldest-used gem materials and have been cherished since pre-history (Hayward, 1960; Demis et al., 2010; Charpentier et al., 2012). Rather than having a geological origin, these gem materials—such as pearls, precious corals and ivory (e.g. Figure 1)—are products of biomineralisation processes in which living animals produce natural substances (i.e. calcium carbonate or which consists of CaCO<sub>3</sub>, as well as proteins, glycosaminoglycans and porosity) (Debevoise et al., 2012). They can be coloured by carotenoids and other types of pigments. Finally, elephant ivory from African (*Loxodonta spp.*) and Asian (*Elephas spp.*) elephant tusks is composed of collagen and carbonate-rich hydroxyapatite (calcite, Ca<sub>5</sub>(PO<sub>4</sub>)<sub>3</sub>CO<sub>3</sub> · H<sub>2</sub>O, Edwards et al., 2006). Ivory can be found in a large number of animal species, of which elephant ivory is the most studied due to its value, recognisability and cultural importance in recent years.

# | REAL CASE IN THE SSEF LABORATORY

Geological age dating of gemstone formation possible in specific cases by using tiny, surface-reaching inclusion minerals.

Zircon in sapphire

Rutile in sapphire

Titanite in ruby

# | REAL CASE IN THE SSEF LABORATORY

## Geological age dating

May support geographic origin determination, as it connects a gemstone to gem deposit formation and plate tectonics.

This ruby of 12 ct from an iconic Harry Winston necklace is approximately 35-40 million years old. The radiometric age dating result is well fitting with the formation of the Himalaya mountain range and the formation of gem deposits in Mogok, Myanmar. # | REAL CASE IN THE SSEF LABORATORY

Documenting (tracking) the treatment status of a gemstone when tested several times in the laboratory, even when submitted by different clients and without indication that the gemstone was already tested before by SSEF.

First submission  
June 2015

cleaned

Second submission  
September 2017

Filled with artificial resin

Third submission  
July 2018

Partly cleaned again

# | REAL CASE IN THE SSEF LABORATORY

Documenting (tracking) of a gemstone in the lab when tested several times, even when recut between submissions and without disclosure that the gemstone was already tested before by SSEF.

First submission  
February 2012

Second submission  
March 2015

Third submission  
June 2018

Fourth submission  
March 2019

# | TRACKING SERVICE BY SSEF: GEMTRACK™

New service by SSEF which links a **cut stone** to a specific **rough stone** using gemmological techniques.

Given the growing demand for provenance and traceability in our industry, the SSEF provides a truly independent gemmological documentation of any gem on its journey from rough to cut and even into jewellery.

# TRACKING SERVICE BY SSEF: GEMTRACK™

## Procedure:

1) Step: Rough stone is tested by SSEF

Stone is cut by client and resubmitted to SSEF

2) Step: Cut stone is compared to data of rough GemTrack™ document added to SSEF Report documenting the journey from rough to cut.

If (new) client sets stone in jewellery

3) Step: Recheck of the mounted stone GemTrack™ document added to SSEF Report documenting the journey from rough to jewellery.

See also <https://www.ssef.ch/gemtrack/>

The image shows a screenshot of an SSEF GemTrack™ document. At the top left is the SSEF logo with a red cross, followed by the text: "SCHWEIZERISCHES GEMMLOGISCHES INSTITUT", "SWISS GEMMLOGICAL INSTITUTE", and "INSTITUT SUISSE DE GEMMOLOGIE". Below this is the title "SSEF GEMTRACK™ DOCUMENT".

There are two photographs of rubies. The left one is labeled "ROUGH RUBY" and "Testing by SSEF". The right one is labeled "CUT RUBY" and "Testing by SSEF (Report No. XXXXXX)".

Below the photos are two tables of data:

Date of Testing:	5 July 2018
Weight:	3.169 ct
Measurements:	10.20 x 7.60 x 6.10 mm

Date of Testing:	28 August 2018
Weight:	1.525 ct
Measurements:	6.46 x 6.29 x 4.27 mm

Below the tables is a section titled "TRACKING RECORD" with three numbered steps:

- 1 Based on the provided documentation, the rough ruby (3.169 ct) described above was mined and recovered in Mozambique and sold at Gemfields auction in Singapore on the 9th of June 2018.
- 2 After the auction, the rough ruby was submitted to SSEF and meticulously analysed and characterized on the 5th of July 2018. The stone was then sent for cutting.
- 3 After cutting, the ruby (1.525 ct) was resubmitted to SSEF and extensively analysed on the 28th of August 2018.

At the bottom, there is a disclaimer: "Based on the consistency of the analysed properties and internal features of the described rough and cut ruby, it is the opinion of the SSEF that the ruby of 1.525 ct described in SSEF Gemstone Report No. XXXXXX was cut from the 3.169 ct rough ruby, tested by SSEF before cutting." Below this is a small image of a GemTrack™ document and the text "Mandatory document verification: www.myssef.ch". At the very bottom, contact information is provided: "Aeschengraben 26 CH-4051 Basel Switzerland - Tel : +41 61 262 06 40 - Fax : +41 61 262 06 41 - admin@ssef.ch - www.ssef.ch".

# TRACKING SERVICE BY SSEF: GEMTRACK™

Gemtrack™ can be easily integrated in existing blockchain solutions.

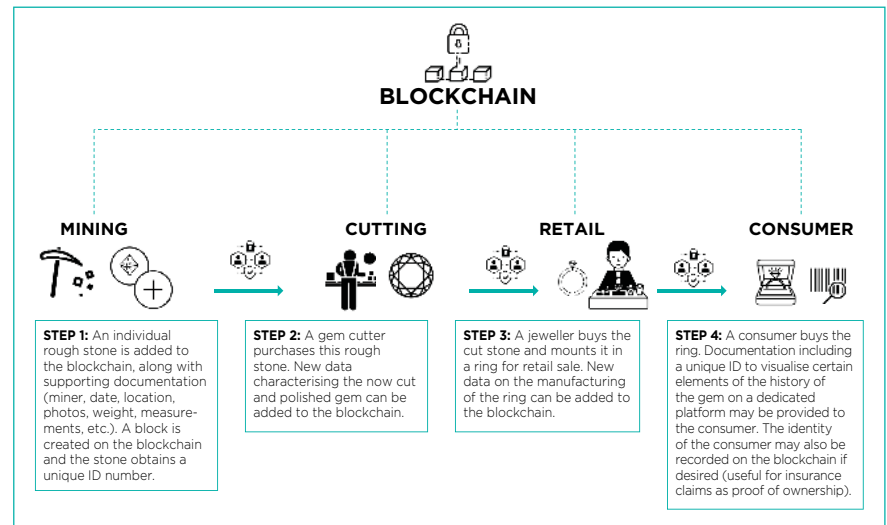

FEATURE ARTICLE

## Blockchain, Chain of Custody and Trace Elements: An Overview of Tracking and Traceability Opportunities in the Gem Industry

Laurent E. Cartier, Saleem H. Ali and Michael S. Krzemnicki

**ABSTRACT:** Recent developments have brought due diligence, along with tracking and traceability, to the forefront of discussions and requirements in the diamond, coloured stone and pearl industries. This is a result of consumer demands for detailed information on the provenance of gems, banking requirements aiming to reduce risk, industry and company initiatives seeking to bring greater transparency, and growing government legislation on mineral supply chains. To address this trend, certification mechanisms and technologies (such as blockchain) are being developed to solve inherent traceability challenges. As applied to gems, such standards and associated technology could benefit from the support of existing gemmological approaches (e.g. geographical origin determination) to enhance traceability and transparency measures. Recent initiatives are not just limited to corporate social responsibility reporting and due diligence requirements, but they also embrace supply chain management (including quality control and process improvements)—for example, to correctly identify and disclose treated and synthetic materials throughout the jewellery industry—as well as address consumer demand for provenance information. This article provides an overview of current trends and developments in the tracking and traceability of gems, along with an explanation of the terms used in this context.

*The Journal of Gemmology*, 36(3), 2018, pp. 212–227, <http://doi.org/10.15506/JoG.2018.36.3.212>  
© 2018 The Gemmological Association of Great Britain

**Figure 4:** This generalised example of a blockchain serves to illustrate how information can be documented on a single gem's journey from mining to cutting and onward to retail and eventually the end consumer. After the stone is mined, the trade and transfer of ownership are validated at each step by both parties involved and recorded immutably to the blockchain. Illustration by L. E. Cartier.

# | CONCLUSIONS

- Origin determination is a scientific deduction process to assess the geographic origin (commonly country/mining area) of a cut gemstone.
- Origin determination from a laboratory provides an independent assessment and may support or exclude origin claims made in documents or by a client.
- Tracing and tracking of gemstones submitted several times to the laboratory is possible.
- SSEF GemTrack™ is a tracking service from rough to cut (and mounted) gems, similar to services offered by other laboratories.
- Integration in blockchain solutions is possible in principle whenever a gemstone is tested in a gemmological laboratory.
